Aim: To create Docker swarm cluster.

Procedure:

1) Use command **docker swarm init** on a node to initialize it as master node.

```
Terminal Host 1 Terminal 3 +
Your Interactive Bash Terminal. A safe place to learn and execute commands.

$ docker swarm init
Swarm initialized: current node (q87tscp7x8ybqhrffxw7t38ja) is now a manager.

To add a worker to this swarm, run the following command:

    docker swarm join --token SWMTKN-1-2i75zops59fhcpvelj356x9ghkctzr37n716gm9qmul5yixxrv-bs780d727uro7b5mv7riav2is 172.17.0.11:2377

To add a manager to this swarm, run 'docker swarm join-token manager' and follow the instructions.
```

2) Copy this docker swarm join --token command and run it on the another node to join it in the swarm cluster and configure it as worker node.

```
Terminal Host 2
Your Interactive Bash Terminal. A safe place to learn and execute commands.

$ docker swarm join --token SWMTKN-1-2i75zops59fhcpvelj356x9ghkctzr37n716gm9qmul5yixxrv-bs780d727uro7b5mv7riav2is 172.17.0.11:2377
This node joined a swarm as a worker.
$ docker ps
CONTAINER ID        IMAGE               COMMAND             CREATED             STATUS              PORTS
```

3) On the master node run command `docker node ls` to see all the nodes that have joined the swarm cluster.

```
$ docker node ls
```

ID	HOSTNAME	STATUS	AVAILABILITY
q87tscp7x8yqbhrffxw7t38ja *	host01	Ready	Active
2929ielz9deqjk04y9nk7gwzz	host02	Ready	Active

4) To create an overlay network via swarm manager node, use command **`docker network create -d overlay app1-network`**.

```
$ docker network create -d overlay app1-network
m6k4kmr8xbowazpaodcpm0e6w
$ docker network ls
```

NETWORK ID	NAME	DRIVER	SCOPE
m6k4kmr8xbow	app1-network	overlay	swarm
a64124b9c3a8	bridge	bridge	local
991a7e8fd0ce	docker_gwbridge	bridge	local
8b89e3388c32	host	host	local
lhgcs9hl6xoz	ingress	overlay	swarm
b3dc159371bf	none	null	local

5) To create a service, use command **`docker service create --network <network-name> -p <port-forwarding> --replicas <replicas> --name`**

<service-name> <image-name>.

```
$ docker service create \
>   --network app1-network -p 80:3000 \
>   --replicas 1 --name app1-web \
>   katacoda/redis-node-docker-example
image katacoda/redis-node-docker-example:latest could not be accessed on a registry to record
its digest. Each node will access katacoda/redis-node-docker-example:latest independently,
possibly leading to different nodes running different
versions of the image.

j8op4dm9hp2c7htgq7expw6bk
overall progress: 1 out of 1 tasks
1/1: running [=====>]
verify: Waiting 2 seconds to verify that tasks are stable...
verify: Service converged
```

6) Use command `docker service ls` to check all the services running.

```
$ docker service ls
```

ID	NAME	MODE	REPLICAS
j8op4dm9hp2c	app1-web	replicated	1/1
katacoda/redis-node-docker-example:latest		*:80->3000/tcp	
bqh3u0uzxb4e	redis	replicated	1/1
redis:alpine			

7) Use command `docker service ps <service-name>` to check the state of the service.

```
$ docker service ps app1-web
```

ID	NAME	IMAGE	ERROR
NODE	DESIRED STATE	CURRENT STATE	
PORTS			
t1adji1ke1e2	app1-web.1	katacoda/redis-node-docker-example:lates	
t host02	Running	Running 50 minutes ago
